INFORMATION REPORT CD NO

Abstract: The purpose of this study was to determine if there were differences in the prevalence of risk factors associated with low back pain between two groups of nurses. One group consisted of nurses who had no history of low back pain and the other group consisted of nurses who had a history of low back pain. A questionnaire was distributed to all participants asking them to report their demographic information, work-related variables, and self-reported health status. Results showed that there were significant differences between the two groups in terms of age, years of experience, type of nursing specialty, and frequency of lifting heavy objects. There were also significant differences in the prevalence of certain risk factors such as smoking, alcohol consumption, and physical activity. The findings suggest that nurses with a history of low back pain are more likely to have certain risk factors compared to those without a history of low back pain.
